Mr Darryl Watkins
Chairperson
Community Consultative Committee
Bowdens Silver Project

Greetings Darryl

## Re: Bowdens Silver Project: Community Consultative Committee 4 May 2022, Response to Questions on Notice

Following the Community Consultative Committee (CCC) meeting held 4 May 2022, Bowdens Silver was provided with two questions on notice from CCC members Mr Bradley Bliss and Mr Michael Boller. There were also four action items that were tasked to RWC to follow up on in the meeting. This letter provides a response to each of these matters for the purpose of addressing the questions from the CCC. We would be pleased to discuss these matters at the next CCC meeting.

## Information Request

In the absence of publicly available and validated, long-term daily rainfall and evaporation records, the Surface Water Assessment (and subsequent updates) prepared by WRM Water and Environment Pty Ltd (WRM) obtained data for the 130-year period between January 1889 to December 2018 from the Scientific Information for Landowners (SILO) data service to assess the Project (refer Section 3.2 of WRM [2022]). SILO is commonly used by hydrological consultants, research agencies such as CSIRO and the Murray-Darling Basin Authority and State agencies. At the most recent CCC meeting Mr Tom Combes noted that he held long-term historical rainfall data collected at Lue Station.

Following discussion with Bowdens Silver, we request that provided Mr Combes is comfortable, he shares that data with us. It would be useful to us to compare this data to that used in the assessment of the Bowdens Silver Project. We have completed a review of the data supplied by Mr Boller but agree that longer-term data would provide a greater point of comparison. We also note that the Lue Action Group submitted to DPE an independent review of the Updated Surface Water Assessment in response to the public exhibition of the Amendment Report: Water Supply. This document, prepared by S. Baguley (Baguley, 2022), provides a graphical presentation of composited recorded rainfall for the Lue area during the period 1887 to 2021 (refer Figure 9 of Baguley [2022]). The long-term data at Lue Station would also enable the preparation of a more meaningful response to the matters raised in Baguley (2022).

## Action Items

Action: $N$. Warren ( $R W C$ ) to review possible influence of exclusion of 2019 rainfall data on outcomes.
Response: Given the SILO dataset used for the assessment spanned 130 years, the inclusion or exclusion of one year does not significantly change assessment outcomes. Long-term data is used so the full range of historical rainfall highs and lows are considered. Review of the SILO data used for the assessment indicates that while 2019 was a low year for rainfall, years of lower rainfall were recorded in the assessment data.

However, to consider this more thoroughly, a comparative analysis of annual rainfall frequencies for both datasets (1889-2018 and 1889-2019) was undertaken using the Log Pearson Type III Distribution method to determine Annual Exceedance Probability (AEP). The results of this analysis on high (99\%) and median (50\%) AEP annual rainfall is provided in Table 1 below. Based on this analysis, $99 \%$ of annual rainfall in the 1889-2018 dataset would exceed $330 \mathrm{~mm} /$ year, with a slightly lower $319 \mathrm{~mm} /$ year for the $1889-2019$ dataset. For $50 \%$ AEP, this difference is almost completely removed. As the $11 \mathrm{~mm}(4 \%)$ difference for $99 \%$ AEP is

| Brooklyn Office | Orange Office | Brisbane Office | ABN: 31002033712 |

minor, it would not substantially change any assessment outcomes for low rainfall periods. This demonstrates that, by capturing a representative range of rainfall distribution, the data utilised by WRM for assessing potential Project-related impacts on surface water resources was entirely suitable.

Table 1

| AEP (\%) | Rainfall (mm/year) |  | Difference |  |
| :---: | :---: | :---: | :---: | :---: |
|  | $\mathbf{1 8 8 9 - 2 0 1 8}$ | $\mathbf{1 8 8 9 - 2 0 1 9}$ | $\mathbf{m m} /$ year | $\%$ |
|  | 330 | 319 | 11 | $4 \%$ |
| 50 | 687 | 686 | 1 | $0 \%$ |

Action: N. Warren (RWC) to provide justification for rainfall level used in low rainfall scenario assessment in the Surface Water Assessment.

Response: Complete assessment of the Project's water supply reliability and impacts requires consideration of the full range of climatic conditions possible over the entire Project-life. This is to properly account for preceding conditions, such as catchment disturbance, rainfall conditions and volumes held in water storages (i.e. carry-over) that could be drawn upon to meet shortfalls. As not all rainfall becomes runoff (generally), WRM tested the site water balance model's sensitivity to low runoff rather than a low rainfall period. This analysis was undertaken by altering the Mine Site catchment's runoff response parameters (refer Table 5.8 of WRM [2022]).

For the modelling assessment, daily rainfall varies throughout the model period and within the ranges of the long-term SILO data. As such, the low runoff scenario applies historical rainfall patterns obtained from the SILO database but assumes that less water is collected in storages (dams) for Project-related use. This is why the low runoff scenario results in a $14 \%$ reduction in water availability.

As the full SILO dataset was used to assess Project-related impacts, water supply security and water management system performance, an annual low rainfall volume cannot be supplied. However, as identified in the table above, the data used for the assessment had a $99 \%$ AEP annual rainfall volume of $330 \mathrm{~mm} /$ year. That is, as in the table above, on most occasions, rainfall exceeded 330 mm .

Action: N. Warren (RWC) to review impacts to water users under low rainfall scenario assessment.
Response: As noted above, the low rainfall scenario referred to in the question is actually low runoff. The change in runoff does not change the worst case assessment of impact. The principal means by which the Project would impact upon Lawsons Creek water users is by increasing the frequency and duration of periods when "cease to take" water access license conditions occur. That is, the conditions of such licences specify when water taken under the licence must cease due to streamflow conditions. During extended periods of low rainfall, all water users would be impacted by these conditions that will occur irrespective of Project approval.

In order to assess impacts of water users under a worst case, WRM assessed the greatest predicted change to "cease to flow" periods. WRM considered the "cease to flow" condition as being Lawsons Creek flows of less than $0.1 \mathrm{ML} /$ day at its confluence with Walkers Creek (refer Location C, Table 8.1 and Figure 8.2 of WRM [2022]). The flow frequency curves for Location C, as derived from the model are presented as Figure 8.3 of WRM (2022). This figure identifies that the Project would add approximately 2 cease to flow days in a given year. This is irrespective of catchment wide rainfall conditions and is in addition to the cease to flow days that would already occur as a result of these conditions.

Action: $N$. Warren ( $R W C$ ) to review extreme high rainfall scenario and what level of rainfall would be needed to cause overflow.

Response: The Mine Site's water management system would be integrated with all dams equipped with pumps and associated infrastructure to transfer water around the Mine Site. This system would be used to meet processing demand and prevent overflow/discharge to the downstream environment. Using the full SILO dataset, WRM assessed the integrated water management system's performance to identify that no discharge would occur. The exception to this was runoff within the clean (undisturbed) water management system (i.e. harvestable rights dams).

The preliminary design of the various water storages within the water management system was based on the following minimum design rainfall events:

- Tailings storage facility: $1 \%$ AEP 72-hour design rainfall $(211 \mathrm{~mm})$ event plus 0.5 metre freeboard in accordance with ANCOLD (2012) ${ }^{1}$. However, this minimum capacity would only be required immediately prior to an embankment raise or toward the end of the facility's operational life. At all other times, capacity would be greater.
- Leachate management dam: $1 \%$ AEP 72-hour design rainfall event ( 217 mm$)^{2}$ plus 1 metre freeboard.
- Processing plant dams: <0.1\% AEP 72-hour design rainfall event ( 345 mm$)^{3}$.
- Sediment dams: 5\% AEP design rainfall event (157mm) with an additional $50 \%$ storage capacity for captured sediment. This design rainfall event significantly exceeds the regulatory design requirements for NSW.
- Clean water (harvestable) rights dams: Varies, water within these dams would be of similar quality to other farm dams in the area and allowed to freely discharge.

## Discussion

The design rainfall events identified above were used to inform preliminary design of the respective minimum storage requirements. All structures have been designed in accordance with, or exceeding, best practice guidelines and standards and have been subject to detailed review by the EPA and DPE Water. Neither agency has raised any concerns with the preliminary design or modelled system performance. As demonstrated by WRM, these structures and their respective storage capacity, coupled with system integration would prevent discharge from the Mine Site under the historical range of rainfall conditions assessed.

In conclusion, the following is also noted.

- The integrated water management system would actively transfer water to maintain design capacities.
- The Project would have the benefit of weather forecasting services for operational water balance modelling that would be used to predict management actions.
- For key containment structures (i.e. the tailings storage facility, leachate management dam and processing plant dams), the preliminary design rainfall event identified above is not recorded in the SILO dataset.
- When considering the preliminary design rainfall levels provided above, with no allowance for management actions, a review of Bureau of Meteorology (BoM) rainfall records identifies:
- No exceedance of the minimum 211mm 72-hour design rainfall event at Mudgee (BoM Station ID 062021, 152-years of record) or Lue (BoM Station ID 062071, 49-years of record);
- One exceedance ( 229.4 mm ) of the minimum 211 mm 72 -hour design rainfall event recorded at Rylstone (BoM Station ID 062026, 141-years of record) between 23 and 25 June 1926; and
- Past exceedances of the 157 mm 72 -hour design rainfall event for sediment dams in all records. However, given their intended use, these structures have a lower risk level.

[^0]Finally, it must be noted that, should the Project be approved, all elements of the Mine Site water management system would be the subject of detailed design that would further assess design rainfall and the risk of discharge to establish final design criteria. Water management is critical to achieving successful operational and environmental outcomes for mining operations and it would be a key focus throughout the life of the Project-life. As these matters are also closely regulated and scrutinised, it is in the best interest of Bowdens Silver to ensure the water management system operates effectively.

## Questions on Notice

Question from Mr Bradley Bliss - When is the Water Pipeline Amendment Response to Submissions date expected?

Response: It is anticipated that the Submissions Report relating to the Water Supply Amendment will be submitted to DPE in September 2022.

Question from Mr Mick Boller - What is the modelled average summer rainfall? Is it 450 mm for 6 summer months?

Response: No. The average summer monthly rainfall for the six-month period from October through March, as derived from the SILO dataset used for modelling was $\mathbf{3 9 2 . 4 m m}$.

Question from Mr Mick Boller - Was the modelled monthly average 75 mm per month in summer?
Response: No. The average summer monthly rainfall from the SILO dataset used for modelling was $\mathbf{6 5 . 3 m m} / \mathbf{m o n t h}$. This average, shown on Figure $\mathbf{A}$ was derived from the monthly averages that are also shown. Figure A also presents the averages recorded by Mr Boller over the period 1987 to 2018.

Figure A: Monthly Average Summer Rainfall: Mine Site SILO (1889-2018) and Boller (1987-2018)

Question from Mr Mick Boller - What were the modelled rainfall totals for the 1978/79, 1988/89,1990/91, 2006/07 and 2014/15?

Response: Figure B presents the SILO dataset rainfall totals for the requested periods that are assumed to relate to seasonal summer rainfall. This figure also presents the rainfall recorded by Mr Boller over the same period (except for 1978/79). Average summer rainfall totals for the full SILO dataset and that of Mr Boller are also provided on Figure B.

Figure B: Selected and Average Summer Rainfall Totals

## Discussion

WRM's long term daily rainfall data obtained from SILO was used for the response to Mr Boller's questions on notice. Rainfall data provided by Mr Boller in his submission to the Department of Planning and Environment (SE-40510577) is also shown in the response for comparative purposes. It is noted that Mr Boller's yearly data was not presented in a consistent monthly format and all effort has been made to ensure it is adequately reproduced. We would be pleased to discuss this further with Mr Boller. For completeness and clarity, Mr Boller's rainfall data in the form it was supplied, and the reproduced dataset drawn from it is also provided.

The information presented on Figure A identifies that, whilst there is some variation in the average rainfall for respective months, when compared with the data provided by Mr Boller, the differences are not significant. In fact, due to the longer period of record, the averages derived from the SILO data ensure a conservative (worst case) approach is taken for the assessment of Project-related impacts to surface water resources. This is demonstrated by the generally higher monthly average rainfall derived from Mr Boller's data that was collected over a (relatively) shorter period. Furthermore, notwithstanding the minor differences in the actual seasonal rainfall totals shown on Figure B (except for 2014/2015), the average rainfalls over summer for both datasets generally align and identify the SILO rainfall data as representative of local conditions and thus suitable for assessing the Project.

## Closure

This response has been prepared and provided to the Community Consultative Committee in good faith and we trust that it is sufficient to address all questions. Bowdens Silver's objective from the outset has been to ensure all matters, including those of significant community interest, such as water resources, are addressed in a comprehensive fashion. Bowdens Silver maintains that the Surface Water Assessment for the Project and subsequent amendments is scientifically robust and has been prepared to the highest level of technical rigour.

We would be happy to discuss any questions regarding this response at the next CCC meeting.

Attached: Table A, rainfall data tabulated from Mr Boller's submission SE-40510577

[^0]:    ${ }^{1}$ Australia National Council on Large Dams (ANCOLD) 2012 - Guidelines on Tailings Dams
    ${ }^{2}$ It is noted that the Bureau of Meteorology's Intensity Frequency Duration website nominates different rainfall depths for the same event at the tailings storage facility and leachate management dam as each has a different geographic grid reference point.
    ${ }^{3}$ Based on combined 100ML capacity.
